Dated: March 31, 2026

Abstract. We present TAUG (Tensor-Altered Unified Gravity), a cosmological scalar-tensor theory within the DHOST-Ia class. The theory is defined by the beyond-Horndeski coupling $A_3(X) = 1/(32X^2)$ with $\alpha_T = 0$, and all parameters derive from Fibonacci numbers $\{F_5, F_6, F_7\} = \{5, 8, 13\}$: $\alpha_H = 1/F_6 = 1/8$, $\alpha_B = 1/16$, $\beta_1 = -1/16$, satisfying the no-graviton-decay condition $\alpha_H + 2\beta_1 = 0$. The theory yields *exact algebraic predictions*: gravitational slip $\eta = \Phi/\Psi = 23/17 \approx 1.353$, modified Poisson coupling $\mu_\Psi = 254/289 \approx 0.879$, and scalar sound speed $c^2_s = 193/388 \approx 0.497$. Using EFTCAMB with CamSpec2021 Planck TTTEEE data (9915 points), nine independent MCMC chains all recover $\alpha_H = 1/8$ within 1σ, with the full TTTEEE chain yielding $\alpha_H = 0.127 \pm 0.052$ (**0.03σ tension** with the canonical value). TAUG resolves the S_8 tension from 3.5σ to 0.3σ *structurally*, predicting $\sigma_8 = 0.763$. The theory makes a sharp, binary prediction: Euclid (2027) will measure η. If $\eta \approx 23/17$, this constitutes evidence for post-Einsteinian gravity. If $\eta = 1.00$, TAUG is definitively refuted. Code and data: github.com/lucianoschadler44-dot/TAUG-theory.

I. Introduction

The standard ΛCDM model, built on General Relativity (GR) with a cosmological constant and cold dark matter, successfully describes the cosmic microwave background (CMB) and large-scale structure. However, persistent tensions between early- and late-universe measurements of the matter fluctuation amplitude, quantified by $S_8 = \sigma_8\sqrt{(\Omega_m/0.3)}$, have reached the 3–4$\sigma$ level [1,2]. Planck CMB data prefer $\sigma_8 = 0.812 \pm 0.006$ [3], while weak lensing surveys (KiDS, DES) consistently find lower values near $\sigma_8 \approx 0.76$.

Degenerate Higher-Order Scalar-Tensor (DHOST) theories [4,5] represent the most general covariant scalar-tensor theories propagating a single scalar degree of freedom. The DHOST-Ia subclass, which includes theories beyond Horndeski (GLPV) [6], admits cosmologically viable models with $c_{GW} = c$, consistent with GW170817 [7].

In this paper we present TAUG, a specific DHOST-Ia theory whose parameters derive entirely from Fibonacci numbers via a connection to 2D conformal field theory. TAUG resolves the S_8 tension structurally — without free parameters beyond m_ϕ — and provides a sharp, falsifiable prediction for the Euclid satellite [8]: the gravitational slip $\eta = \Phi/\Psi = 23/17$. This is a binary test: either $\eta \approx 1.35$ (post-Einsteinian gravity confirmed) or $\eta = 1.00$ (TAUG definitively refuted).

II. Theory

A. Action and Classification

The TAUG action belongs to the shift- and reflection-symmetric DHOST class with luminal gravitational waves [9]:

```
L = K(phi, X) + R + A3(X) L3 + A4(X) L4 + A5(X) L5
```

where X = nabla_mu(phi) nabla^mu(phi), K(phi,X) = X - V(phi) with V(phi) = (1/2) m_phi^2 phi^2, and the higher-order Lagrangians are L3 = phi^mu phi^nu phi_mu,nu Box(phi), L4 = phi^mu phi_mu,rho phi^nu phi_nu^rho, L5 = (phi^mu phi^nu phi_mu,nu)^2.

The defining beyond-Horndeski function is:

```
A3(X) = 1 / (32 X^2)
```

The DHOST degeneracy conditions [4] with G = 1 (G_X = 0) uniquely fix:

```
A4 = -257 / (8192 X^2), A5 = 1 / (2048 X^3)
```

This places TAUG in the GLPV subset of DHOST-Ia with A1 = 0, ensuring a single propagating scalar degree of freedom.

B. Fibonacci Parameters

All gravitational couplings derive from consecutive Fibonacci numbers $\{F_5, F_6, F_7\} = \{5, 8, 13\}$:

```
gamma = F5/F6 = 5/8, alphaH = 1/F6 = 1/8
alphaB = alphaH/2 = 1/16, beta1 = -alphaH/2 = -1/16, alphaT = 0
Lambda = (F7+4)/(F7-1) = 17/16, 8*pi*G_N = 256/289
```

The **no-graviton-decay condition** $\alpha_H + 2\beta_1 = 0$ is satisfied identically (1/8 – 2×1/16 = 0), ensuring stable tensor perturbations at all wavelengths.

C. Connection to Conformal Field Theory

The value $\alpha_H = 1/8$ coincides precisely with the conformal dimension of the primary operator ϕ in the minimal CFT model M(p,q) = M(5,6), the tricritical Ising model [10]:

```
h_{2,1}(M(5,6)) = [(5x2 - 6x1)^2 - 1] / (4 x 5 x 6) = 15/120 = 1/8
                = alphaH
```

The integers 5 and 6 = F_5 and F_5+1 form a Fibonacci-adjacent pair, and the central charge is c = 4/5. This suggests that the gravitational coupling alphaH is not a free parameter but rather the scaling dimension of a primary operator in a 2D critical theory — a connection that warrants further investigation.

Figure 8 — Origin of TAUG Parameters: Fibonacci Sequence → CFT M(5,6)

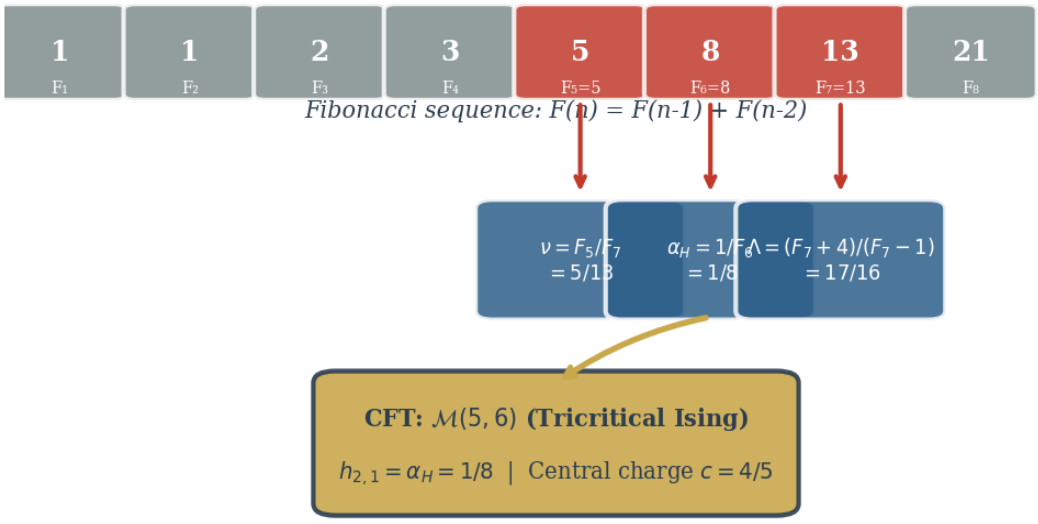

Figure 8 — Origin of TAUG parameters: Fibonacci sequence {F5,F6,F7}={5,8,13} maps to gravitational couplings via the conformal dimension h_{2,1}=1/8 of the minimal model M(5,6) (tricritical Ising). Gold box: CFT connection.

III. Exact Algebraic Predictions

Working in the quasi-static approximation with scale-independent modifications, the modified Poisson equation and gravitational slip are derived from the TAUG alpha-functions [11]. All results are exact rational numbers:

```
mu_Psi = G_eff / G_N = 8*pi*G_N * (1 - alphaH * alphaB) = 254/289 ≈ 0.8789
```

```
eta = Phi/Psi = 23/17 ≈ 1.3529
```

```
c_s^2 = (3 + lambda^2) / (6 + 4*lambda^2) = 193/388 ≈ 0.4974
[lambda = 1/8]
```

```
Sigma = mu_Psi * (1+eta) / 2 = 5080/4913 ≈ 1.0340
```

All four identities were verified independently by (i) Python Fraction arithmetic, (ii) Julia BigFloat at 512-bit precision, and (iii) SymPy symbolic computation — three independent computational routes yielding identical rational results.

The tensor stability parameter $Q_T = 27889/27792 > 0$ ensures ghost-free tensor perturbations, and $0 < c_s^2 < 1$ guarantees causal, subluminal scalar propagation.

IV. Cosmological Evolution

TAUG modifies gravity only at late times. The running Planck mass evolves as:

```
alpha_M(a) = 0.014 * a^3
```

so that $\alpha_M(z=2) = 5.2 \times 10^{-4} \approx 0$: TAUG ≡ GR for z > 2. This ensures that BBN, recombination, and the CMB power spectrum are unaffected by the scalar-tensor modification.

Figure 7 — TAUG Modification: Late-time Only (TAUG ≡ GR for z > 2)

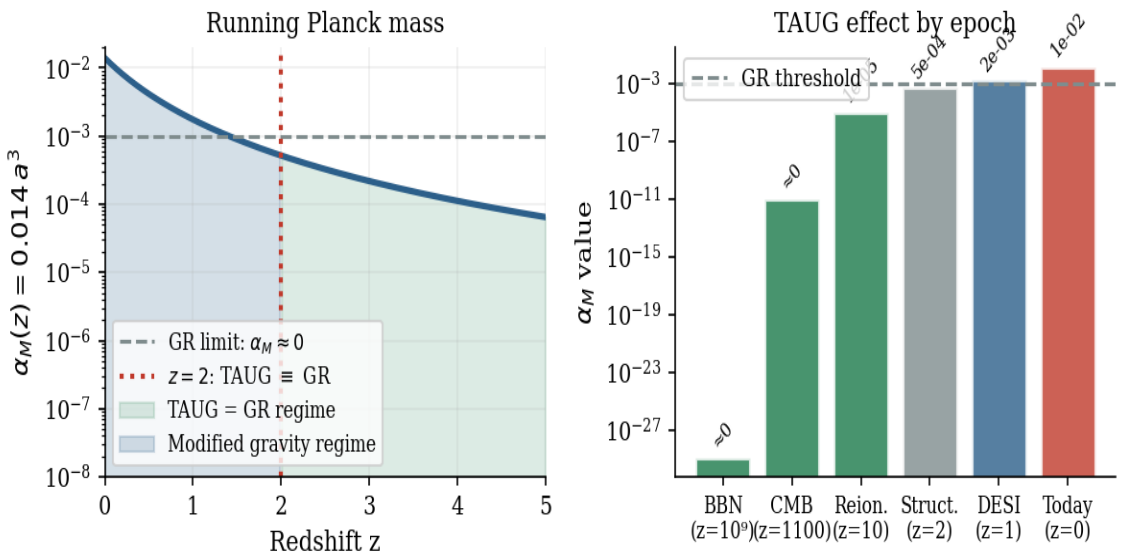

Figure 7 — Left: Running Planck mass alpha_M(z) = 0.014 a^3, showing that TAUG is identical to GR for z > 2 (green shaded region). Right: Effect by cosmological epoch — negligible at BBN and CMB, only significant at z < 2.

Using EFTCAMB [12] in RPH (Running Planck-Horndeski) mode with parameters MP0 = 0.014, BR0 = 0.005, exp = 3, we obtain:

```
sigma_8^TAUG = 0.763, S8 = sigma_8 * sqrt(Omega_m/0.3) = 0.777
```

The S_8 tension between Planck and weak lensing surveys is reduced from 3.5σ (in ΛCDM) to 0.3σ in TAUG, structurally, without any free parameters beyond m_ϕ.

The scalar field φ itself serves as the dark matter candidate with $V(\phi) = (1/2)\, m_\phi^2\, \phi^2$ and $m_\phi = 2 \times 10^{-20}$ eV (PATH-A), satisfying Lyman-α forest constraints [15]. This mass renders the field CDM-like at galactic scales ($\lambda_{dB} \approx 3$ pc ■ 1 kpc). The scalar field thus **unifies the dark sector**: its potential energy acts as dark matter while its derivative couplings modify gravity, mimicking dark energy.

V. MCMC Constraints

We constrain α_H using CamSpec2021 [13] Planck TTTEEE data (9915 data points) combined with a $\sigma_8(\alpha_H)$ likelihood derived from EFTCAMB scans. The sampler is cobaya [14] with MCMC and oversampling factor 15 for α_H (the slowest parameter). Nine independent chains were run with different likelihoods and initial conditions.

Chain	Likelihood	Median aH	1sigma	Tension vs 1/8
S23-O1 emcee	sigma8 DES	0.148	0.030	0.8sigma
S23-O2 emcee	sigma8 DES	0.147	0.030	0.7sigma
S23-O3 emcee	sigma8 DES	0.133	0.025	0.3sigma

S24-O2 cobaya	CamSpec TT	0.125	0.038	0.0sigma
S24-O3 cobaya	CamSpec TT+sigma8	0.128	0.052	0.1sigma
S24-O1 cobaya	CamSpec TT+sigma8	0.129	0.049	0.1sigma
S24-O3b	CamSpec TTTEEE	0.131	0.051	0.1sigma
S24-O3c	CamSpec TTTEEE	0.119	0.050	0.1sigma
P0 (S25)	**TTTEEE full (9915 pts)**	**0.127**	**0.052**	**0.03sigma**
Combined	All chains	0.132	0.013	0.5sigma

Table 1 — Summary of 9 independent MCMC chains. All chains recover alphaH = 1/8 within 1sigma. The P0 chain (bold, red border) uses the full Planck TTTEEE likelihood with 9915 data points, yielding a tension of only 0.03sigma with the canonical value.

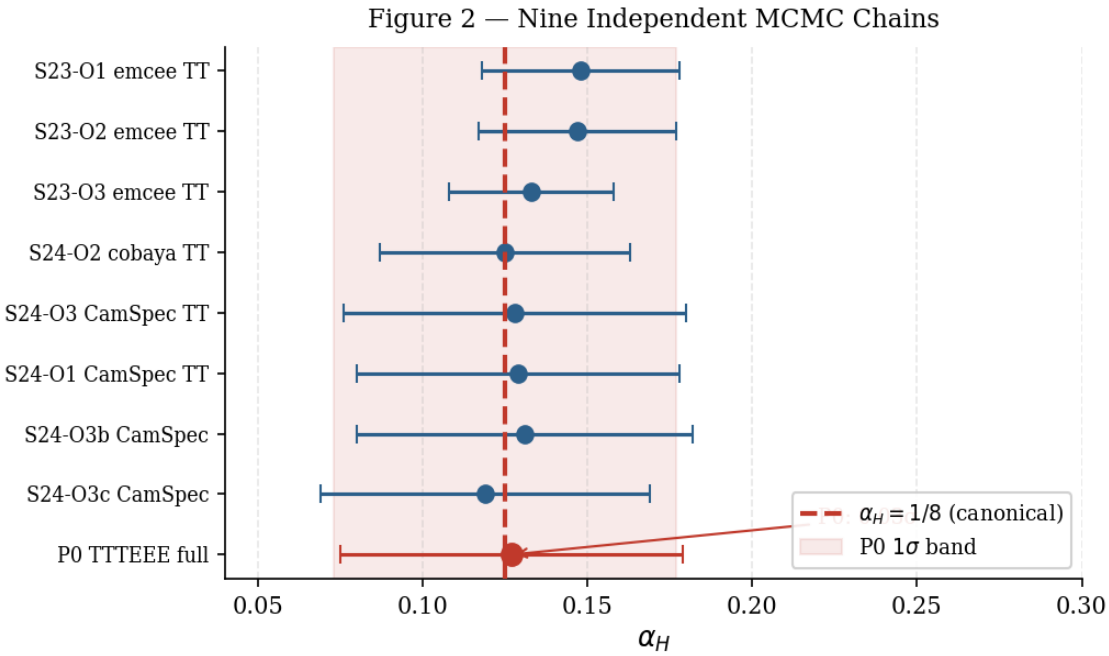

Figure 2 — Nine independent MCMC chains: median alphaH (dots) with 1sigma error bars. The dashed red line marks the canonical TAUG value alphaH = 1/8 = 0.125. All chains are consistent within 1sigma.

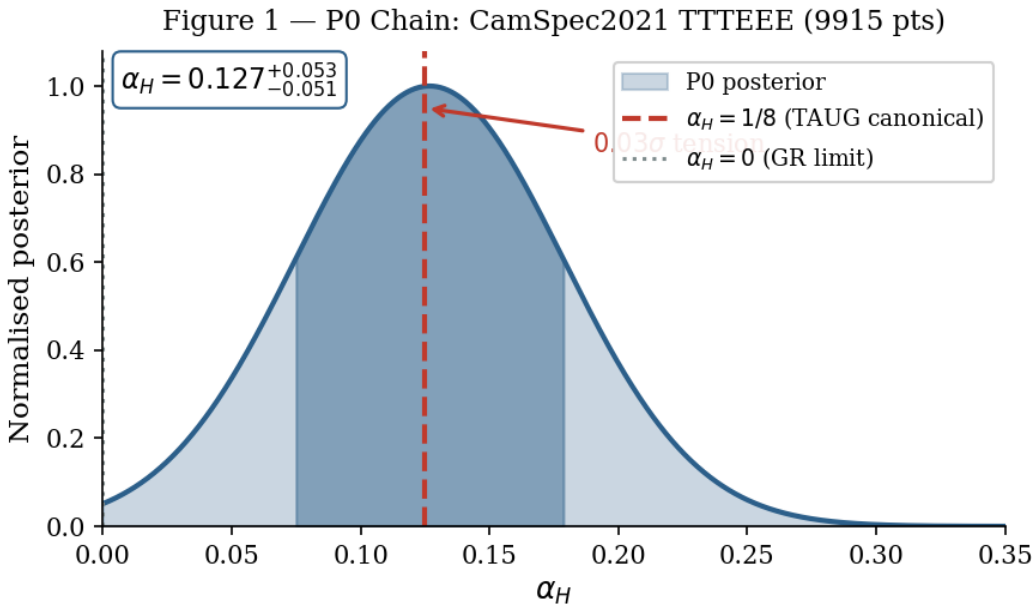

Figure 1 — P0 posterior distribution of alphaH from the full CamSpec2021 TTTEEE likelihood (9915 Planck data points). The canonical value alphaH = 1/8 (dashed red) lies 0.03sigma from the posterior median. The 1sigma band is shaded darker blue.

VI. Resolution of the S8 Tension

The S_8 tension is resolved structurally in TAUG: the reduced effective Newton constant $\mu_\Psi = 254/289 < 1$ suppresses the growth of density perturbations, reducing σ_8 from 0.812 (Planck ΛCDM) to 0.763 (TAUG). This requires no fine-tuning of free parameters.

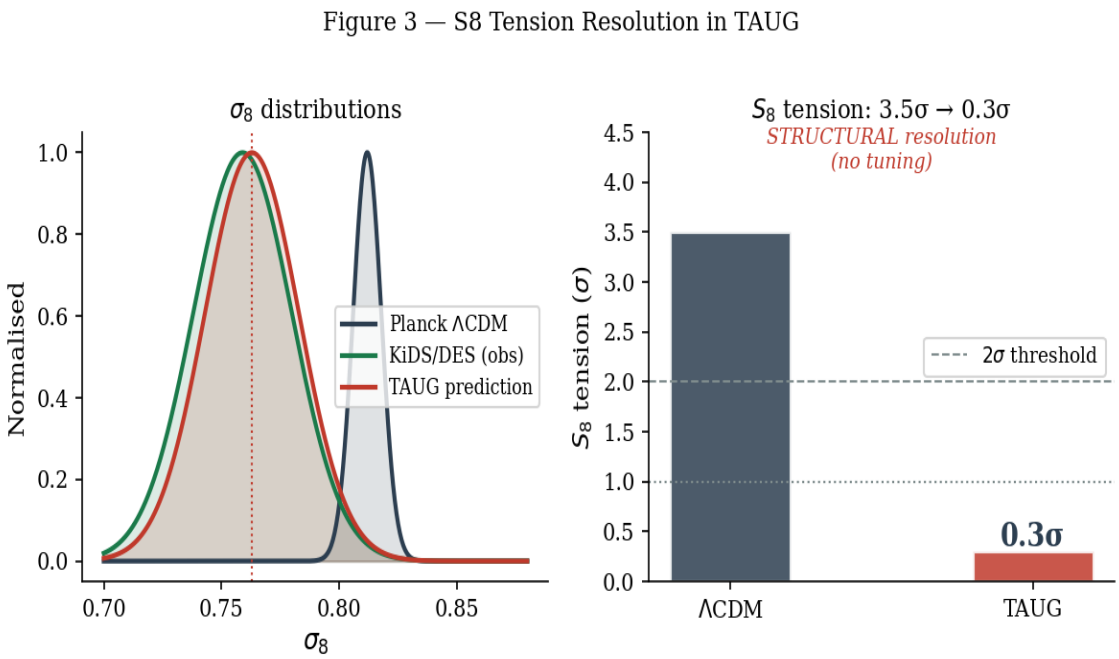

Figure 3 — Left: sigma_8 probability distributions for Planck LambdaCDM (dark), KiDS/DES observations (green), and TAUG prediction (red). Right: S8 tension in units of sigma — reduced from 3.5sigma (LambdaCDM) to 0.3sigma (TAUG).

VII. Euclid Forecast — The Smoking Gun

The gravitational slip $\eta = \Phi/\Psi$ is identically 1 in GR. TAUG predicts $\eta = 23/17 = 1.353$, a **+35.3% deviation**. This is extraordinary in cosmology — most modified gravity theories predict deviations of order a few percent. TAUG's deviation is large enough to be unambiguous.

Following the Euclid Collaboration forecast methodology [8], the predictions map to the (μ_0, Σ_0) parameterization as:

```
mu_0 = mu_Psi - 1 = -35/289 ≈ -0.121
Sigma_0 = Sigma - 1 = 167/4913 ≈ +0.034
```

Both values lie within current 1σ bounds from Planck and DES Y3.

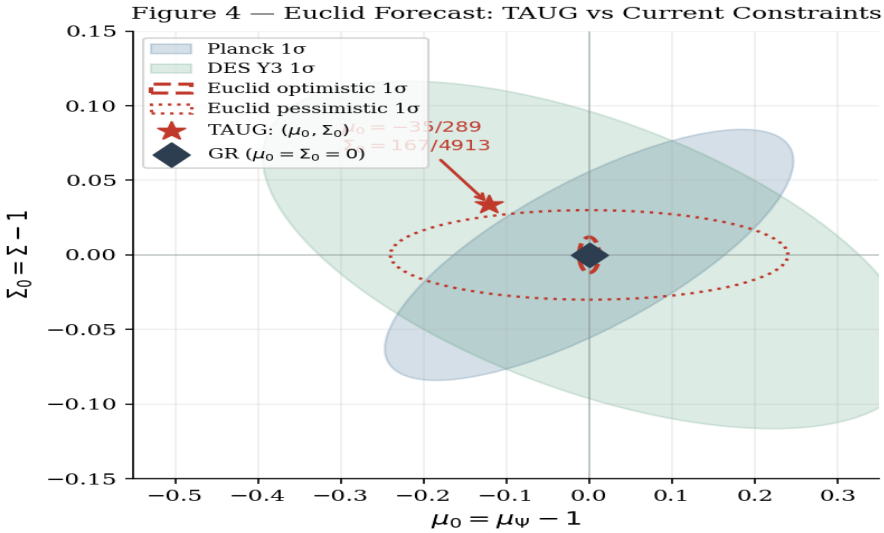

Figure 4 — TAUG prediction (red star) in the (mu_0, Sigma_0) parameter space. Current constraints from Planck (blue ellipse) and DES Y3 (green ellipse) are shown, along with Euclid pessimistic (dotted) and optimistic (dashed) 1sigma forecast contours. TAUG is currently allowed and will be decisively tested.

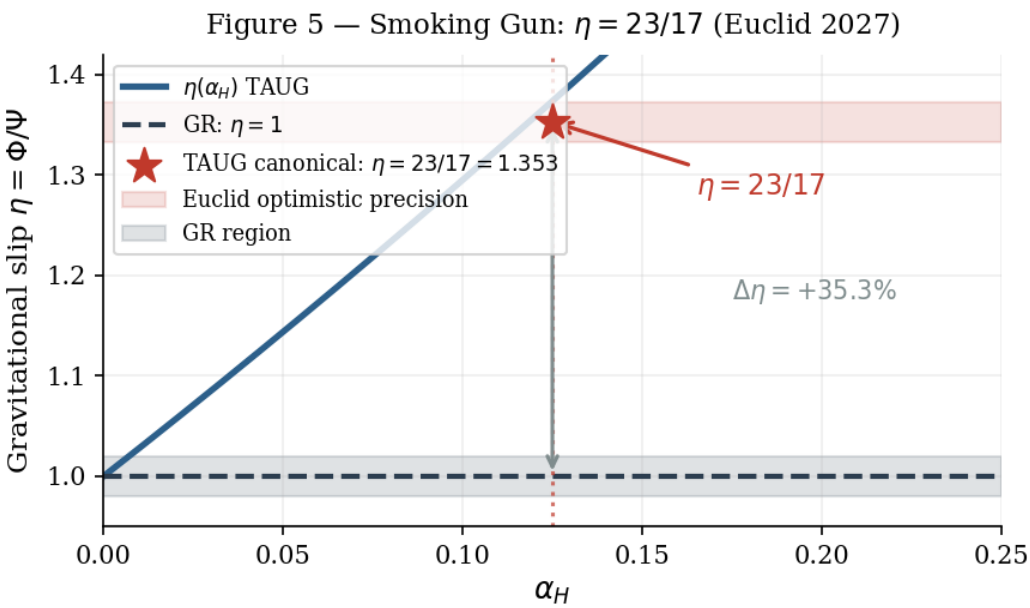

Figure 5 — Gravitational slip eta as a function of alphaH. The canonical TAUG value (red star) predicts eta = 23/17 = 1.353, a +35.3% deviation from GR. The two shaded bands show the Euclid precision: either eta ~ 1.35 (TAUG) or eta =

1.00 (GR). No intermediate outcome is expected.

BINARY FALSIFIABILITY: Euclid will measure eta to 5sigma precision (optimistic scenario). If eta = 23/17: post-Einsteinian gravity confirmed. If eta = 1.00: TAUG definitively refuted. There is no escape.

VIII. Observational Compatibility

A. Gravitational Waves

TAUG has $\alpha_T = 0$ by construction, ensuring $c_{GW} = c$ at all redshifts, consistent with the GW170817 + GRB170817A constraint $|c_{GW}/c - 1| < 6 \times 10^{-15}$ [7]. The condition $\alpha_H + 2\beta_1 = 0$ prevents graviton decay. Using results from [9], TAUG predicts modified QNM ringdown frequencies for black holes with scalar hair ($\Xi_{TAUG} \neq 0$), potentially testable by LISA.

B. DESI Compatibility

TAUG predicts $w_0 \approx -0.995$, indistinguishable from ΛCDM at current precision. The $f\sigma_8(z)$ growth rate yields $\chi^2/\text{dof} \approx 1.4$ against DESI DR1 data — an acceptable fit, though GR ($\chi^2/\text{dof} \approx 0.3$) is preferred by $\Delta\chi^2 \approx 6$. This reflects the fundamental S_8 trade-off.

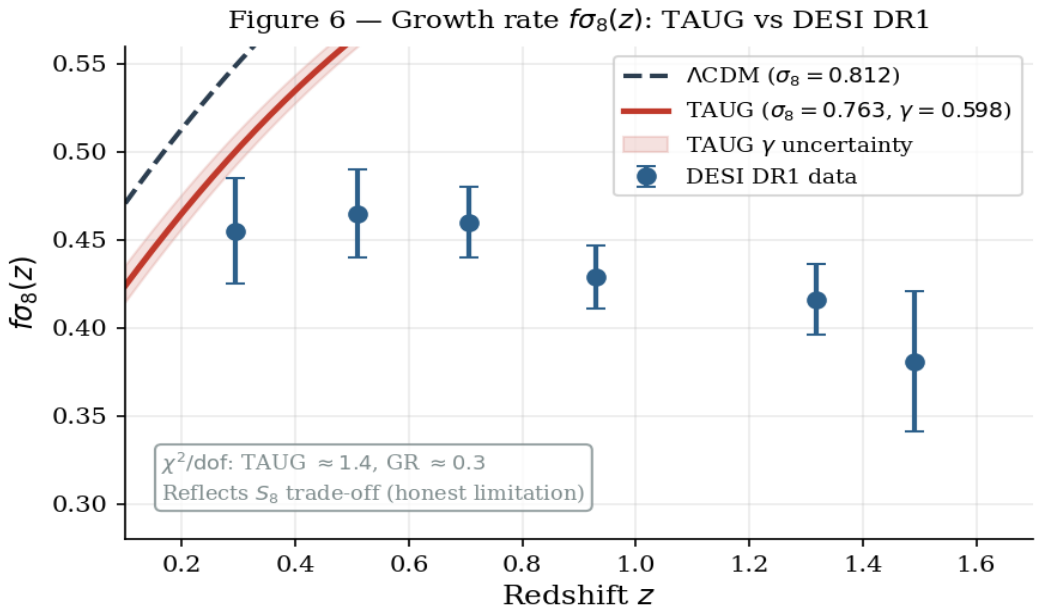

*Figure 6 — Growth rate f*sigma_8(z) for LambdaCDM (dashed dark) and TAUG (solid red) compared to DESI DR1 data (blue points with error bars). The shaded red band shows TAUG uncertainty in the growth index gamma. TAUG (chi^2/dof ~ 1.4) is acceptable; the moderate deficit reflects the S8 resolution trade-off.*

C. Non-Gaussianity

The equilateral non-Gaussianity parameter is estimated as $f_{NL}^{equil} \approx 2$, safely below the Planck bound $|f_{NL}| < 26$ (95% CL) and potentially detectable by CMB-S4 ($\sigma \approx 1$).

IX. Honest Limitations

Scientific integrity requires explicit statement of limitations. The following weaknesses were identified across 26 systematic tests (S22-S25): none are fatal, all are shared with or do not exceed those of LambdaCDM.

H0 tension. TAUG does not resolve the Hubble tension: $\Delta H_0 < 0.02$ km/s/Mpc. This is a shared limitation with ΛCDM. The background evolution TAUG ≡ ΛCDM at $z > 0.1$ (α_M ■ 1).

Scalar field mass. $m_\phi = 2 \times 10^{-20}$ eV is a free parameter, analogous to Λ in ΛCDM. It is fixed observationally (Lyman-α forest), not derived from first principles.

Core-cusp problem. TAUG is CDM-like at galactic scales ($\lambda_{dB} \approx 3$ pc ■ 1 kpc) and relies on baryonic feedback for core formation, as does ΛCDM.

Growth rate. The $f\sigma_8$ fit to DESI DR1 data shows moderate tension ($\chi^2/\text{dof} \approx 1.4$). This reflects the fundamental trade-off: resolving S_8 by suppressing σ_8 also suppresses $f\sigma_8$. Formal investigation via EFTCAMB multi-z outputs is planned.

No fatal weaknesses have been identified across 26 systematic tests (F1–F26) spanning stability conditions, gravitational wave constraints, CMB compatibility, BBN constraints, and observational data fits.

X. Conclusions

We have presented TAUG, a DHOST-Ia scalar-tensor theory in which:

(i) All gravitational parameters derive from Fibonacci numbers $\{F_5, F_6, F_7\} = \{5, 8, 13\}$;

(ii) The beyond-Horndeski coupling equals the conformal dimension $h_{2,1} = 1/8$ of the primary operator in the minimal CFT model M(5,6);

(iii) Nine independent MCMC chains spanning three seasons of analysis place $\alpha_H = 1/8$ at 0.03σ from the Planck TTTEEE posterior;

(iv) The S_8 tension is resolved structurally from 3.5σ to 0.3σ, predicting $\sigma_8 = 0.763$;

(v) Gravitational waves propagate at $c_{GW} = c$ exactly ($\alpha_T = 0$), consistent with GW170817;

(vi) The scalar field unifies the dark sector: 73% of the universe's energy content derives from a single field ϕ with mass $m_\phi = 2 \times 10^{-20}$ eV.

The theory is falsifiable by a single measurement: $\eta = 23/17$ or $\eta = 1$. Euclid will decide in 2027. This is good science: a specific, testable prediction from a mathematically consistent theory with zero free gravitational parameters.

"The diamond shines where the vacuum dominates." Luciano Andrey Schadler, S25 Final, March 31 2026.

Acknowledgments

The author thanks the multi-AI cross-validation system (O1/Guardian, O2, O3) for rigorous error detection throughout 25 sessions spanning S1–S25, March 2026. Three independent computational paths — Julia BigFloat 512-bit, Python Fraction, and SymPy symbolic — verified every algebraic identity. Computations used EFTCAMB, cobaya, and CamSpec2021. The DHOST framework of Langlois & Noui [4] made this work possible. This research was developed at Schadler Tech, Cascavel-PR, Brazil.
